PREFACE

- Below is a list of the Sections in SPS 4 that were revised since December 1, 2003.

a) **Revised Sections Effective Dec. 1, 2005**
   - Section 6.1;
   - Section 7.13;
   - Section 9.33;
   - Section 13.6.1.2;
   - Table 4;
   - Section 15.2.2.2;
   - Section 15.4.2.2.1;
   - Section 16.3; and
   - Appendices VIII, IX & XII

b) **Revised Sections Effective Dec. 1, 2006**
   - Section 9.3.4;
   - Section 14.1;
   - Section 15.4.2.2;
   - Figure 4 - Action 1; and
   - Appendix IX.

c) **Revised Sections Effective Nov. 1, 2010**
   - Section 2.1 - added “HRA” and “Spot-Check” definitions and updated the “Interchangeable” definition;
   - Section 2.2 - updated the “Reference Publications”;
   - Added new Section 3.4; and
   - Section 14.2 & 14.3 – Added “Spot-check” references

d) **Revised Sections Effective March 9, 2011**
   - Replaced all references to Fingerjoined “Flange Stock Lumber (FJ-FS)” to “Fingerjoined Machine Graded Lumber (FJ-MGL)” throughout this document;
   - Section 1.5 updated Note;
   - Section 2.1 - added definitions for “FJ-MGL”, “Dry Use Only”, updated the “Heat resistant adhesive” definition and deleted the FJ-FS definition;
   - Section 2.2 - “Reference Publications” added ASTM D73704-08 & CSA-0112.10;
   - Section 3.1;
   - Table 1 – Revised grade names and deleted Comp. Parallel to Grain columns;
   - Section 7.1.1;
   - Added Section 7.1.3.2; and
   - Added Section 10.1.4.

e) **Revised Sections Effective February 1, 2013**
   - Table 6 - added “or load cell” to the “once a week - Bending Proof Loader” requirement to now read “and once a week with a proof ring or load cell”.
   - Replaced “Calibration” in the Table 6 heading with “Spot-Check” to now read: “Table 6 - Test Equipment Spot Check Frequency”.
   - Section 13.3 - added (To be performed by the Facility) to the section title; and
   - Section 13.4 - added (To be performed by the Agency) to the section.

f) **Revised Sections Effective November 1, 2014**
   - Updated Section 2.2 Reference Publications
   - Revised Section 13.6.1.4 to improve wording of this clause;
1.0 SCOPE

1.1 PART A & PART B
This Standard consists of two parts.

PART A:
Product Specifications: specifies grade characteristics, standard sizes, visual grading and mechanical property requirements, property evaluation procedures, and grade stamping requirements for Fingerjoined Machine Graded Lumber (FJ-MGL).

PART B:
Qualification and Quality Control Requirements: specifies minimum qualifications and quality control requirements for a facility producing FJ-MGL in accordance with the requirements of Part A of this Standard.

1.2 NLGA STANDARD GRADING RULES
This Standard shall be used in conjunction with and forms part of the NLGA Standard Grading Rules for Canadian Lumber.

1.3 IMPERIAL UNITS
In case of a dispute, the values stated in imperial units shall take precedence.

1.4 MACHINE GRADED LUMBER
This Standard has been established to permit production of FJ-MGL where the lumber segments have been machine graded prior to fingerjoining.

1.5 FINGERJOINED MACHINE GRADED LUMBER (FJ-MGL)
This Standard applies to Fingerjoined Machine Graded Lumber (FJ-MGL), in which the quality of the fingerjoint is established by inspection and test procedures and the quality of the full-length fingerjointed lumber, is established in accordance with the appropriate sections of this Standard.

Note: The requirement of this standard does not supersede or replace any responsibility or obligation of the component manufacturer to ensure full compliance with appropriate end use standards.

2.0 DEFINITIONS & REFERENCED PUBLICATIONS

2.1 DEFINITIONS
The following definitions shall apply to this Standard.

AGENCY: an organization accredited by the Canadian Lumber Standards Accreditation Board (CLSAB) and/or the American Lumber Standard Committee Board of Review engaged in the grading, grade stamping and/or certification of lumber or who certifies facilities to grade and place a grade stamp upon lumber.

AGENCY SUPERVISOR: an employee of the Agency who is approved by the Agency to inspect facilities producing FJ-MGL.

AGENCY VERIFICATION: a specific set of procedures used by an Agency to verify that an item of post grade stamped FJ-MGL conforms to the requirements of this Standard and the NLGA Standard Grading Rules.

BOIL OUT: a characteristic of phenol-resorcinol adhesives cured at high temperatures: the paraformaldehyde hardener decomposes to gaseous formaldehyde more rapidly than the formaldehyde can react with the phenol-resorcinol resin. Unless sufficient pressure is applied to the glueline, the result may be a foamy glueline that is weaker than a normal glueline.

CALIBRATION: a procedure of comparing two instruments, measuring devices or standards, one of which is of known accuracy traceable to a nationally recognised standard.

CHARACTERISTIC NUMBER OF JOINTS (CNJ): the number of fingerjoints present in an 8-foot section of FJ-MGL. This value is determined as follows:

\[
CNJ = \frac{8 \times N}{L}
\]

Where \( N \) is the number of fingerjoints in the specimen and \( L \) is the overall length of the specimen in feet. \( CNJ \) shall be rounded up to the nearest whole number and shall not be less than 1.

CHARACTERISTIC PROPERTY VALUE: the value corresponding to a percentile in the assumed statistical distribution of a particular property of the material. For the purpose of this standard, characteristic strength values (i.e. UTS) are defined as the population 5th percentile values obtained under a short-term test load. Characteristic stiffness values (i.e. \( E_{\text{th}} \), \( E \)) are defined as the population 5th percentile or mean values obtained under a short-term test load.

CONFORMANCE: a state in which the production process meets the requirements of this Standard.

CONTROL CHARTS: are reports or records used to monitor the variation between the process quality level and a predetermined conformance quality level, and to indicate when changes in the process are required to bring the process back into an in-control state as defined by the conformance quality level.

CYCLIC DELAMINATION TEST: a test procedure that simulates environmental conditions to which wood products may be exposed during shipment, storage or use.

DELAMINATION: a separation of the glueline as a result of drying stresses. Reasons for delamination may also include joint mis-manufacture that produces a glueline that is weaker than the wood or delamination may be caused by the glueline being softened by the water. Drying stresses that produce delamination are similar to those that produce checking in wood.
DISPLACEMENT: the amount of clear wood displaced by a characteristic and considered in its relation to the amount it reduces the strength of the cross-section of the piece of lumber under consideration.

DRY USE ONLY: Product is to be used only under dry service conditions as defined in the applicable engineering design standard.

Note 1: In Canada, a dry service condition is defined in CSA O86 as a climatic condition in which the average equilibrium moisture content of solid wood over a year is 15% or less and does not exceed 19%.

Note 2: In the US, a dry service condition is defined in the National Design Specification (NDS) as a climatic condition where the lumber moisture content in service will be a maximum of 16%.

EVALUATION: an assessment of the manufacturing process and its quality control programs to determine whether a facility is capable of producing an item that meets the requirements of this standard.

FACILITY: is a manufacturing plant that produces–FJ-MGL and conducts visual grading and quality control sampling and testing.

FINGERJOINED MACHINE GRADED LUMBER (FJ-MGL): lumber that has been non-destructively tested by a grading machine such as MSR lumber or MEL, and is fingerjoined to meet the product specifications of this Standard.

GAUGE LENGTH: the length of lumber between the inside edges of the tension machine grips that is subject to the full tension load. The procedures and requirements specified in this Standard are based on an assumed gauge length of 8 feet.

GRADE STAMP (MARK): the grade identification applied on a specimen of FJ-MGL shall include the appropriate information under Section 10.0 of this Standard. The grade stamp (mark) indicates that the FJ-MGL process meets the requirements of the Agency’s qualification and quality control procedures.

GRADING MACHINE: any CLSAB and ALSC approved and certified equipment used to sort lumber into mechanical property classes (e.g. stiffness classes).

HEAT RESISTANT ADHESIVE (HRA): an adhesive that meets the ASTM D7374 acceptance criteria for elevated temperature performance.

HORIZONTAL FINGERJOIN: a profile formed so that an image of the fingers appears on the narrow face of the lumber.

IN-CONTROL: a state in which on-going quality control testing indicates that the production process meets the mechanical property or delamination requirements of this Standard.

INCREASED (DOUBLE) SAMPLING: random sampling undertaken to generate 2 - five-specimen samples from every four hours or less of production, for a period of three production shifts. Specimens thus obtained shall be tested and test results analysed and recorded in accordance with the quality control requirements of this Standard.

INSPECTION: the examination, measurement and/or testing of the properties of an item to ensure they meet the quality control requirements of this Standard.

INTERCHANGEABLE: capable of being assigned the design values of another product under certain end-use conditions.

Note 1: The specific end-use conditions are described in this Standard.

Note 2: Two products are deemed to be interchangeable only to the extent established by the minimum requirements specified in this Standard. Comparability of properties not explicitly covered by this Standard may require additional assessment.

ITEM: lumber of a given grade, size (without reference to length), species or species group and moisture content.

LUMBER ASSESSMENT: tests conducted on fingerjoined lumber randomly selected from production.

MACHINE EVALUATED LUMBER (MEL): is lumber that has been non-destructively evaluated by a grading machine and meets the MEL requirements of SPS 2.

MACHINE STRESS-RATED (MSR) LUMBER: is lumber that has been non-destructively evaluated by a grading machine and meets the MSR requirements of SPS 2.

MODULUS OF ELASTICITY (MOE): the ratio of stress to corresponding strain below the proportional limit. In this standard, the modulus of elasticity is determined in bending at a span of 21 times the depth and tested in accordance with ASTM D198. The dressed size (net finished size) is used in computing the modulus of elasticity.

NON-CONFORMANCE: a deficiency in a property, documentation or procedure that renders the quality of an item not to be in adherence to specified requirements of this Standard and therefore unacceptable. Examples that may cause non-conformance: physical defects, test failures, incorrect or inadequate documentation, or deviations from prescribed processing, inspection or test procedures.

OUT-OF-CONTROL: a state in which on-going quality control testing indicates that the production process does not meet the mechanical property or delamination requirements of this Standard.

QUALITY CONTROL: a set of procedures that provide a means of measuring and regulating the characteristics of an item to specified requirements.

QUALITY CONTROL MANUAL (PLANT STANDARD): a document which sets forth a specific set of instructions to describe the quality control functions and requirements to be carried out in the production of FJ-MGL.

RANDOM SAMPLING: a procedure by which a sample is generated from a population. The sample shall be representative of the population.
RE-QUALIFICATION: analysis of the test results from a random sample drawn from a process that has undergone corrective action in response to an "OUT-OF-CONTROL" condition or re-establishing conformance of non-production grades for a period exceeding one year of a particular FJ-MGL grade.

SEPARATE-APPLICATION ADHESIVE: a multi-component adhesive that has the following characteristics:

- Each adhesive component is applied separately to one or both sides of the joint.
- All adhesive components are required for the bond strength to be fully developed.
- Some separate-application adhesives require that the components be blended in order for the adhesive to develop the required strength and durability. Other systems simply require the components to come into contact with each other.

1 *Blended* is defined as thoroughly mixing the adhesive components together resulting in a homogeneous mixture.

SHIPMENT: one or more bundles, packages or units of lumber that comprise an order.

SPECIFIC GRAVITY (SG): is the weight of the substance relative to the weight of an equal volume of water. This is also commonly known as relative density. The specific gravity (SG) is based on the mass and volume of the wood at the oven-dried moisture content.

SPECIMEN: a piece of full size FJ-MGL randomly selected from production once the piece has been tension proof-loaded for purposes of quality control, quality verification testing and any subsequent analysis.

SPOT CHECK: the verification that the calibration / device / machine are still within calibration tolerances.

SUBSEQUENT QUALIFICATION: analysis of the test results from a random sample drawn from a process whose production is in-conformance with the requirements of this Standard, but has been modified for reasons other than to respond to a detection of non-conformance. Subsequent qualification procedures apply only to the process changes specified in this Standard. Other process changes shall be evaluated using the initial Qualification procedures.

TENSION JOINT ASSESSMENT: tension tests conducted on the characteristic number of consecutive joints from one or more pieces of fingerjoined lumber.

TENSION PROOF-LOADING: is a process whereby a piece(s) of fingerjoined lumber is loaded to a predetermined proof load tensile stress level.

TEST EQUIPMENT: equipment used by the facility to determine the modulus of elasticity (MOE), resistance to delamination of a finger joint and the ultimate tensile strength (UTS) for the purpose of determining conformance to the specified requirements of this Standard.

TEST LOAD: a load that will induce a stress that corresponds to the characteristic property value for the grade under consideration.

TYPE A CANDIDATE STOCK: non-fingerjoined lumber that has met all of NLGA SPS 2 qualification and quality control requirements for the MOE of an equivalent or higher MSR lumber grade.

TYPE B CANDIDATE STOCK: non-fingerjoined lumber that has met all of the NLGA SPS 2 qualification and quality control requirements of an equivalent or higher MSR lumber grade.

VERTICAL FINGERJOINT: a profile formed so that an image of the fingers appears on the wide face of the lumber.

WOOD FAILURE: a type of failure induced on the glue bond in which the fingerjoint is failed by the tearing away of wood fibre from one and / or the other side of the fingerjoint of the two pieces that have been glued.

Note: If fingers break off at the base or away from the fingerjoint, this is not considered to be wood failure.

**REGULATIONS** (Oct. 2013)
PART A - PRODUCT SPECIFICATIONS FOR FINGERJOINED-MACHINE GRADED LUMBER (FJ-MGL)

3.0 PRODUCT DESCRIPTION

3.1 GENERAL

Fingerjoined Machine Graded Lumber (FJ-MGL) is a product comprised of multiple pieces of lumber or segments that has been non-destructively evaluated by a grading machine prior to fingerjoining. FJ-MGL produced to the requirements of this Standard is interchangeable with other lumber products. FJ-MGL cannot be visually re-graded or re-manufactured into a higher stress grade even if the quality of the lumber containing fingerjoints would otherwise warrant such re-grading.

Where FJ-MGL is joined with an adhesive for limited moisture exposure (See commentary to CSA O112.10) the product is marked “DRY USE ONLY”. Such products are only to be used in applications where the in-service moisture content of the wood will not exceed 19%.

Fingerjoining of chemically treated lumber or chemical treatment of fingerjoined lumber are not within the scope of this Standard.

Qualification and subsequent quality control of the modulus of elasticity (MOE), and ultimate tensile strength (UTS) are required for each item.

Lumber represented, as conforming to the requirements of this Standard shall be manufactured by a process in which the quality of FJ-MGL is produced in accordance with all of the requirements specified herein.

Product conformance shall be documented by the maintenance of records and charts on the results of the inspection and test procedures.

Note: It should be noted that the Qualification and subsequent Quality Control procedures are both based on two processes: 1) an assessment of the FJ-MGL quality; and 2) a separate assessment of the fingerjoin quality. The MGL is also assessed following the procedures of SPS 2.

3.2 CANDIDATE LUMBER STOCK

3.2.1 GENERAL

The candidate lumber stock shall not contain any fingerjoints.

This standard applies to two type of candidate stock designated as Type A and Type B as defined below:

3.2.1.1 TYPE A

The candidate lumber stock used in the assembly of FJ-MGL, shall have met the qualification and quality control requirements for MOE in accordance with NLGA SPS 2 requirements for the grade(s) being produced as specified in Table 1.

The plant layout, production sequence and identification of the candidate stock shall be described in the Quality Control Manual and shall ensure that all segments in the final product originate and can be verified to have originated from production that meets the NLGA SPS 2 requirements for MOE of the grade being produced.

3.2.1.2 TYPE B

The candidate lumber stock used in the assembly of FJ-MGL, shall have met all of the qualification and quality control requirements in accordance with NLGA SPS 2 requirements for the grade(s) being produced as specified in Table 1.
The plant layout, production sequence and identification of the candidate stock shall be described in the Quality Control Manual and shall ensure that all segments in the final product originate and can be verified to have originated from production that meets the NLGA SPS 2 requirements of the grade being produced.

Note: FJ-MGL processed with Type B candidate stock that results in a CNJ of greater than one (1) shall be processed as Type A candidate stock in this Standard.

3.3 OVERSIZE LUMBER

Because candidate stock is first machine graded, it is permissible for the lumber to be machine graded in an oversized condition to allow for re-surfacings of the lumber after the fingerjoining process. When candidate stock is oversized, the grading machine shall be calibrated to account for the greater cross-sectional area of the lumber and the MOE test equipment results shall be corrected to account for this greater cross-section area.

3.4 SPECIAL APPLICATIONS

3.4.1 HEAT RESISTANT ADHESIVES

Fingerjoined lumber marked “HRA” is manufactured with a heat resistant adhesive that meets the requirements of ASTM D7374. Fingerjoined lumber marked as “HRA” and used in non-standard fire rated assemblies may require additional fire protection.

Note: See ASTM D7374 for background on standard fire-rated assembly.

4.0 GRADE DESCRIPTION

FJ-MGL grades are designated by a MGL grade that references a specific set of characteristic properties values.

The grades of FJ-MGL produced in accordance with this Standard are listed in Table 1.

5.0 STANDARD SIZES

Standard thickness and widths for FJ-MGL produced in accordance with this Standard are shown in Table 2. Other thickness and widths can be used on qualification.

| 2400Fb-2.0E  | 2400Fb-2.0E                                               | 2,000,000                        | 13,789                             | 1,640,000                       | 27.9                              | 2,560                            | 17.7

Specific gravity values are assigned as follows (See NLGA SPS 2):

**Douglas Fir-Larch (N):**

- SG values are a function of the grade E
  - 1.2E to 1.9E SG = 0.49
  - 2.0E to 2.2E SG = 0.53
  - 2.3E & higher SG = 0.57

**Spruce-Pine-Fir (FJ):**

- SG values are a function of the grade E
  - 1.2E to 1.7E SG = 0.42
  - 1.8E to 1.9E SG = 0.46
  - 2.0E and higher SG = 0.50

**Hem-Fir (N):**

- SG = 0.46 (all grades)

6.0 VISUAL REQUIREMENTS

6.1 MACHINE GRADED LUMBER SEGMENTS

6.1.1 GENERAL

Prior to fingerjoining, the Machine-Graded lumber segments shall be well manufactured and visually graded to limit defined characteristics on the FJ-MGL product even though the actual strength may not be affected. Characteristics permitted and limiting provisions shall be:

Checks: Seasoning checks not limited. Through checks at ends are limited as splits.

Manufacture: Standard F (See NLGA Para. 722 f).

Shake: If through at ends - limited as splits.

Away from ends - through shakes - up to 2 feet long, well separated.

If not through - single shakes shall not exceed 3 feet or 1/4 the length, whichever is the greater.

Skips: Hit and miss, with a maximum of 5% of the pieces containing hit or miss or heavy skip 2 feet or less in length (See NLGA Para. 720).

Slope of Grain: For grading machines not evaluating slope of grain, the limitation on general slope of grain is based on the characteristic UTS value assigned to the grade and is the same as in Table 4.

Splits: Equal in length to 1-1/2 times the width of the piece.

Wane: 1/3 the thickness and 1/3 the width, full length, or equivalent on each face, provided that wane not exceed 2/3 thickness or 1/2 the width for up to 1/4 the length. See NLGA Para. 750.

White Specks: 1/3 face or equivalent

6.1.2 VISUAL QUALITY LEVEL (VQL)

In addition to the visual limitations listed above, other strength reducing characteristics such as knots, knot holes, burls, abnormal grain distortion or decay partially or wholly at the edges of wide faces, shall not occupy more of the net cross-section than the Visual Quality Level limits listed for the characteristic UTS values assigned in Table 3.

6.1.3 CROSS-SECTION OR KNOTS OTHER THAN EDGE KNOTS FOR TYPE A CANDIDATE STOCK

For Type A candidate stock, cross-section knots or knots other than edge knots shall not exceed the size or displacement of the edge knot permitted in the next lower edge knot classification.

Table 3 – VQL Limits for FJ-MGL

6.2 ESTABLISHING ALTERNATE VISUAL QUALITY LEVELS

Strength reducing characteristics larger than those listed in Sections 6.1.2 and 6.1.3 may be permitted provided the additional requirements of 13.2 are followed. In such cases, the limiting size of the strength-reducing characteristic shall be documented.
6.3 SPECIES
The lumber used in the manufacture of FJ-MGL may be of any species in the species combinations specified in the NLGA rules. These species may be combined in any combination that preserves the species combination. Species from different species combinations shall not be mixed within the same specimen.

6.4 WOOD QUALITY IN THE JOINT
6.4.1 For all grades of FJ-MGL, the fingerjoints shall be formed in sound wood that otherwise meets the slope of grain and other visual requirements of the grade, except as provided for in Sections 6.4.2 and 6.4.3.

6.4.2 In all grades, the fingers shall not contain knots that exceed 10% displacement. Knots appearing on the narrow faces are permitted the same cross-sectional area displacement as knots specified on wide faces (10%). All knots exceeding 10% displacement shall be set back from the base of the fingers so that neither the knot(s), nor the grain distortion associated with the knot(s) extend into the fingers.

6.4.3 Wane - shall not exceed half the thickness in any grade. Wherever possible, the wane on the two pieces forming the joint shall be placed at the same corner of the joint.

6.5 FINGER PROFILE
The orientation of the finger profile may be manufactured into the lumber at any angle; however, the finger profile shall be formed in a plane at right angles to the longitudinal axis of the lumber being joined.

6.6 FINGERJOINT TOLERANCES
The tolerances on machining and assembly of the finger profile shall be such that when the end pressure and the face pressure are applied in the gluing process (make-up), the following conditions are met:

a) The tip gap, which is the distance from the tip of any finger in the joint area to the base of the matching profile for that finger, must not exceed \( \frac{1}{16} \) " (1.6 mm).

b) Fingerjoint offset between the surfaces of the lumber, in either a lateral or vertical direction, must not exceed \( \frac{1}{16} \) " (1.6 mm).

Note: The spacing between the gluing surfaces on either side of the fingers is such to reduce glue boil out in the joint area during the curing process. Boil out may occur on surfaces adjacent to the outside fingers because of inadequate pressure.

6.7 MOISTURE CONTENT
Green and dry lumber shall not be mixed within the same specimen.

7.0 FINGERJOINT REQUIREMENTS

7.1 ADHESIVE SPECIFICATION

7.1.1 GENERAL
The adhesive shall meet either Section 7.1.2 or Section 7.1.3 in addition to Section 7.1.4.

7.1.2 RESORCINOL & PHENOL RESORCINOL ADHESIVES
The adhesive used for joining of the fingerjoints shall meet the requirements of CSA-O112.7-M1977, Resorcinol and Phenol-Resorcinol Resin Adhesives for Wood.

The adhesive may be mixed with the minimum amount of inert fillers required for its performance in the particular process being used.

7.1.3 ALTERNATE ADHESIVES
7.1.3.1 The adhesive used for joining of the fingerjoints shall meet the requirements of CSA-112.9-10 or CSA-O112.10-08 when evaluated for one of the softwood species specified in the Standard.

7.1.3.2 FJ-MGL joined with an adhesive that meets only CSA-O112.10-08 shall also be grade marked “DRY USE ONLY”.

7.1.4 ELEVATED TEMPERATURE
The adhesive used for joining of the fingerjoints shall meet the requirements of ASTM D7374-08.

7.2 “SEPARATE APPLICATION” ADHESIVES

7.2.1 GENERAL

7.2.1.1 NON-PERMISSIBLE SEPARATE-APPLICATION” ADHESIVES
“Separate application” adhesives are not permitted when components, which are applied separately, need to be blended in order for the joint to achieve the required bond strength and durability.

7.2.1.2 PERMISSIBLE “SEPARATE APPLICATION” ADHESIVES
“Separate application” adhesives utilising additional components that only require contact between the components in order to develop the required bond strength and durability are permitted provided the requirements of Sections 7.2.2 and 7.2.3 are met.

7.2.2 MONITORING REQUIREMENTS
In addition to meeting the requirements of Section 7.2.1.2, the following information shall be provided and documented in the Plant Standard:

a) Procedures for continuous monitoring of the proportions of the components applied to joint, and the coverage required for each component;

b) Systems for notifying the operator when the component proportions or coverage are beyond the acceptable limits as defined in the adhesive specification. Acceptable operating limits shall be qualified under Section 7.2.3;
7.3 QUALIFICATION

Prior to performing the qualification requirements outlined in Section 13.8.3, the procedures outlined in Section 13.4.2 shall be used to qualify both the upper and lower limits of that provided in the adhesive specification.

Joints shall be sampled as specified in Section 13.4.2 from production set to operating conditions corresponding to the upper component proportions or coverage and tested in accordance with Section 13.4.2. This sampling and testing shall be repeated for production set to operating conditions corresponding to the lower component proportions or coverage.

7.3 ADHESIVE MIXING

Mixing of the adhesive shall be performed in accordance with the instructions of the adhesive supplier.

7.4 JOINT FABRICATION

7.4.1 ADHESIVE APPLICATION

The adhesive shall be applied to the finger profiles in a manner that will ensure that all of the gluing surfaces between the fingers receive a sufficient amount of adhesive that result in squeeze out of excess glue when the end pressure is applied. The adhesive may be applied to one or both sections forming the joint.

7.4.2 HEAT DAMAGE

The procedure used to apply heat to the finger profile shall be such as to ensure that neither the wood surfaces in the finger profile nor the wood itself are not damaged by excess heat.

Note: In Radio Frequency (RF) curing, wood damage may result from excessively long exposure of the finger profile to the RF field. When the wood is pre-dried in a kiln, excessive drying temperatures (above 350°F or 175°C) may reduce the strength of the wood. In either situation both the strength and the long-term durability of the joint may be impaired. Brush breaks may be an indication of heat damage.

7.4.3 END PRESSURE

The end pressure applied during the joint assembly process and while the glueline is being cured, shall be that required for the particular lumber size, species, finger profile and process used.

Pressure shall not be such as to produce splitting in the wood at the base of the fingers.

8.0 MECHANICAL PROPERTY REQUIREMENTS FOR FINGERJOINED - MACHINE GRADED LUMBER (FJ-MGL)

The following requirements shall apply to the characteristic property values listed in Table 1.

8.1 MEAN MODULUS OF ELASTICITY

The process mean edge bending modulus of elasticity (E) tested in accordance with Section 9.1.1 shall equal or exceed the characteristic mean modulus of elasticity value for the grade E (Eg).

\[ E \geq E_g \]

8.2 MINIMUM MODULUS OF ELASTICITY

The process lower fifth percentile for edge bending modulus of elasticity (E₅₉) for Table 1 FJ-MGL grades tested in accordance with Section 9.1.1 shall equal or exceed 0.82 times the characteristic mean modulus of elasticity value for the grade E (Eg).

\[ E_{5th} \geq 0.82E_g \]

9.0 PROPERTY EVALUATION PROCEDURES

The test methods described in this Section conform to either ASTM Standards D198 or D5055.

9.1 FINGERJOINED MGL EVALUATION

9.1.1 MODULUS OF ELASTICITY (MOE) – LUMBER ASSESSMENT

Specimens shall be tested on edge using third point loading and a span to depth ratio of 21.

The specimen depth is the surfaced dry width as provided in Table 2.

Modulus of Elasticity shall be determined using load and deflection data collected at load levels less than the specimen proportional limit.

Specimens shall be centred in the test span. The edge, which is to be subjected to tension stress, shall be randomly selected.

9.1.2 ULTIMATE TENSILE STRENGTH (UTS) – LUMBER ASSESSMENT

UTS - Lumber Assessment testing is required for FJ-MGL that uses Type A candidate stock (Section 3.2.1.1) and for Type B candidate stock, where the characteristic number of joints (CNJ) exceeds 1 (See Section 3.2.1.2).
For off-line tensile strength testing, the ultimate tensile strength (UTS) shall be determined by applying a test load that will induce a maximum stress not less than the characteristic UTS value for the grade under consideration.

Specimens shall be tested using a gauge length (test span) of at least 8 feet (2.44 m) whenever the test sample lengths permit.

The maximum strength reducing characteristic, as determined by visual grading, shall be positioned within the test span and, whenever possible, at least a minimum of two times the nominal test specimen width away from grips.

If the maximum strength-reducing characteristic is found to be located partially or wholly within the grips, the specimen shall be replaced.

The load shall not induce a rate of stress increase that will exceed 4,000 pounds per square inch per minute (0.46 MPa/sec).

Specimens that carry the test load without fracture or with only partial failure, meet the test requirements. If a specimen fails before the test load has been achieved, the load at failure shall be recorded.

Note: The producer has the option of using the samples that are tested to failure for the characteristic number of joint assessment or ignoring samples that have been load tested in the lumber evaluation if they are not tested to failure.

### 9.2 JOINT STRENGTH EVALUATION PROCEDURES

#### 9.2.1 ULTIMATE TENSILE STRENGTH (UTS) - JOINT ASSESSMENT

**9.2.1.1 UTS SPECIMEN SIZE**

A sufficient number of full-size FJ-MGL specimens shall be selected to permit, where possible, the characteristic number of consecutive joints in a specimen to be tested as described in Section 9.2.1.2.

If additional joints are required to complete the CNJ UTS - joint assessment test, they shall be selected from full-size supplemental specimens selected consecutively from production and consecutive joints from the supplemental specimens and shall be tested as described in Section 9.2.1.2.

**9.2.1.2 UTS TEST PROCEDURE**

a) Except as noted in Section 9.2.1.2f), the gauge length shall be between 1 and 2 feet, but not less than 4 times the largest cross-section dimension.

b) The fingerjoint shall be centred in the test span and loaded in tension to failure. The load shall not induce a rate of stress increase that will exceed 4,000 pounds per square inch per minute (0.46 MPa/sec).

c) A UTS joint assessment shall be carried out for each specimen in the sample.

d) The number of joints tested per UTS joint assessment shall be equal to or greater than the CNJ to be qualified or evaluated.

e) The joints tested shall be those contained in the specimen plus any additional joints selected consecutively from supplemental pieces of FJ-MGL.

f) Except for joints positioned wholly or partially in the tension grips, joints evaluated under Section 9.1.2 may provide results for the UTS joint assessments provided the specimen is loaded to failure. Only joints located at least two (2) times the largest cross-section dimension away from the grips shall be considered.

g) Substitution of results for joint tests with failure occurring away from the fingerjoint is permitted (See Appendix IV - Mode 6). Results from the next closest available joint on the same specimen, if possible, shall be used.

### 9.2.1.3 UTS CALCULATION & REPORT

The UTS joint assessment result for each specimen shall be the minimum joint test result obtained from the specimen and any additional joints from supplemental pieces of FJ-MGL necessary to obtain the minimum number of joint tests for that specimen.

The tensile strength assigned to each of the joints evaluated under Section 9.2.1.2f) shall be the UTS of the specimen obtained in lumber assessment.

### 9.3 DELAMINATION RESISTANCE EVALUATION

#### 9.3.1 DELAMINATION TEST SPECIMEN

Green lumber shall be dried to 19% or less moisture content prior to performing the delamination test.

**9.3.1.1 FINGER PROFILES GREATER THAN 5/8" (16 mm) IN LENGTH**

The test specimen shall consist of a section of the fingerjoined lumber approximately 7 inches (180 mm) long with the fingerjoint in the centre of the length. The specimen shall be cross cut through the centre of the joint to yield two test specimens.

**9.3.1.2 FINGER PROFILES 5/8" (16 mm) & LESS IN LENGTH**

The fingers of the test specimen shall be cross cut at the tips of the fingers to yield one test specimen approximately 3½” (89 mm) in length with the glueline visible in the end grain.

#### 9.3.2 DELAMINATION TEST PROCEDURE

Place the test specimens in the pressure vessel and weight them down. Admit sufficient water at a temperature of 65 to 85°F (18.3 to 29.4°C), so that the test specimens are completely submerged.

Separate the test specimens by stickering, wire screens or other means so that all end grain surfaces are freely exposed to water.

Draw a vacuum of 20 to 25 inches (508 to 635 mm) of mercury and hold it for 30 minutes, then release the vacuum and apply a pressure of 75±5 psi (0.520 ± 0.034 MPa) for a period of two hours.
Dry the test specimens using air at a temperature of 160±5°F (71±3 °C). The air circulation and number of specimens in the oven at any one time shall be selected such that the specimens are dried to moisture content of 19% or less.

During drying, place the specimens at least 2 inches (50 mm) apart, with the end grain surfaces and finger orientation parallel to the direction of the airflow. (Refer to Appendix VII)

Dry the specimens until the moisture content (MC) of each specimen has reached 19% or less. Measure and record the delamination immediately, following the procedures set forth in Section 9.3.3.

Note: In ordinary circumstances drying the specimens overnight (up to 18 hours) should achieve the desired drying, provided the drying chamber is functioning as specified.

9.3.3 MEASUREMENT OF DELAMINATION

At the end of the drying period, immediately examine the crosscut surface of the specimens for separations of the bondlines and probe any indeterminate areas with a 0.004-inch (0.102-mm) feeler gauge.

All bondline separation shall be considered as delamination except for the following:

a) Ignore any separation in the bondlines adjacent to the outer fingers, any separation less than 0.10 inch (2.5 mm) long, and any separation within the knot boundaries visible in the crosscut surface.

b) Where glue skip is present, it is permitted to ignore to a maximum of 10% of the total bondline that is shown to be due to glue skip. Such samples shall be marked to indicate the glue skip and the records shall show the amounts deducted from the delamination calculations.

Note: Action should be taken to identify the causes of and prevent glue skip in the joint. If glue skip is suspected, the joint should be opened and the bondlines examined. The use of aids such as indicator dyes and appropriate lighting should be used to identify areas where adhesive is not present.

Measure the length of the delaminated portions to the nearest 1/16-inch (1.6 mm). Add the various lengths together.

Note: Testing should be done immediately because if the delamination specimens are removed from the oven and allowed to pick up moisture from the atmosphere, the bondline separation will tend to close up.

9.3.3.1 INITIAL QUALIFICATION, RE-QUALIFICATION & RE-INSPECTION TESTING

If the delamination of any specimen or, if applicable, the average delamination of a specimen and its matching specimen (Section 9.3.1.1) after one vacuum, pressure and drying cycle exceeds 5% but is less than 10%, repeat the above vacuum, pressure, drying cycle twice on that specimen and its matching specimen (if any), and record the delamination at the end of the third cycle.

9.3.3.2 QUALITY CONTROL & VERIFICATION TESTING

Results from daily quality control, verification, and re-inspection test specimens shall be reported after one cycle of vacuum, pressure and drying.

9.3.4 DELAMINATION CALCULATION & REPORT

The percentage delamination of a specimen is the sum of all the delamination found (excluding the outermost gluelines), divided by the total length of all the gluelines in which the delamination was measured, times 100.

Report the percentage delamination of each specimen, the average percentage delamination for the joint.

9.3.4.1 When delamination in a fingerjoint exceeds 10%, the fingerjoint shall be sawn from the wood and the gluelines cleaved open, so determine the cause of delamination. Causes of delamination shall be included in the quality control report.

Note: In facilities that use RF heating of the glueline, the exposed cross-section of the test specimens may show any overheating of the joint area as a discoloration of the wood. Most commonly, delamination is caused by glue skip, but may also result from heat damage to the gluing surfaces. Heat damage may result in delamination to an area that shows shallow wood failure. A poorly manufactured finger profile may also contribute to delamination.

9.3.4.2 The Agency as part of its “Fingerjoint Policies and Procedures“ may request a facility to hold the delamination test samples intact for examination.

9.4 TENSION PROOF-LOADING

All fingerjoints shall be proof loaded by applying a tensile stress for the species, size and grade as provided in Table 1.

Note: Occasional fingerjoints that appear near the ends and fall within the grips may be excluded from this requirement. However, production processes where the fingerjoints are consistently located within the grips shall not be permitted.

9.5 ENVIRONMENTAL CONDITIONS

9.5.1 MEASUREMENT OF MOISTURE CONTENT AT TIME OF TEST

For each UTS joint assessment test specimen, a moisture content measurement using a resistance type moisture meter shall be made on each side of the joint and sufficiently back from the base of the joint so that the meter readings are not influenced by the presence of the adhesive.

Each of the readings shall be recorded as the moisture content of the specimen(s) segment at the time of test.

9.5.2 TEMPERATURE

9.5.2.1 EQUIPMENT

The temperature of the test equipment shall, at the time of the test, be in the range of 10 to 30°C (50 to 90°F) inclusive.
If the proof loading equipment is operated at temperatures below 10°C (50°F), the equipment shall be calibrated at a temperature within ±5°C (10°F) of the temperature at which the equipment will be operated.

9.5.2.2 FINGERJOINT TEST SPECIMENS
Test specimens shall be stored under the same environmental conditions (within ±5°C or ±10°F) as the production until the start of the fingerjoint tensile strength and/or delamination test.

9.5.2.3 FJ-MGL TEST SPECIMENS
All strength and stiffness evaluations shall be performed on test specimens that have a temperature range of 10 to 30°C (50 to 90°F) inclusive.

### 10.0 GRADE STAMPING REQUIREMENTS

#### 10.1 GENERAL FOR FJ-MGL

10.1.1 A grade stamp on FJ-MGL indicates that the grading process meets the requirements of the Agency's qualification and quality control procedures.

10.1.2 All previous grade stamps shall be removed or obliterated.

10.1.3 For FJ-MGL produced in conformance with the requirements of this Standard, the grade stamp on each product shall contain items as noted in Table 5.

10.1.4 Where FJ-MGL is joined with an adhesive that meets CSA-O112.10-08 only, the product shall also be marked “DRIY USE ONLY”.

[1] The maximum VQL if the requirements of Section 13.2 are met.

[2] For the example: -4 means ¾ edge knot was qualified.

[3] Where FJ-MGL is joined with an adhesive that meets only CSA-O112.10-08, the pieces shall also be marked “DRIY USE ONLY”.

Note: If the “optional” items are marked on the grade stamp, the facility shall follow additional quality control procedures.
PART B - QUALIFICATION & QUALITY CONTROL REQUIREMENTS

11.0 EQUIPMENT

The facility’s grading machine and test equipment shall meet the following requirements:

11.1 GRADING MACHINE

A grading machine (if applicable) shall be of a make and model for which an Agency application to the CLSAB and ALSC has been made and approval has been granted.

11.2 QUALITY CONTROL TEST EQUIPMENT

The test equipment shall be capable of accurately measuring the mechanical properties described in Part A of this standard. The equipment shall be certified by an independent certification organisation.

Note: The use of load and deflection measuring devices that are accurate to within 1% of the actual measurement are preferred.

11.2.1 MOE TEST EQUIPMENT ACCURACY

The test span and the location of the load points shall be capable of being set to within ±1/16-inch (1-mm).

The device used to measure deflection shall be capable of measuring to the nearest 0.001-inch (0.01-mm).

The deflection and load measuring devices shall be accurate to within ±2% of the actual measurement.

The load shall be applied through a crosshead.

The rate of crosshead movement shall not exceed 5 inches per minute (2 mm/second) during specimen testing.

11.2.2 TENSION TEST EQUIPMENT ACCURACY

11.2.2.1 OFF-LINE UTS TEST EQUIPMENT

The test span shall be set to within ±3 inches (75 mm) of the specified test span. The load-measuring device shall be accurate to within ± 2% of the actual load.

The rate of load application shall not exceed 4,000 psi per minute (0.46 MPa per second) during specimen testing.

11.2.2.2 TENSION PROOF LOADER

The load-measuring device shall be accurate within ± 2% of the actual load.

The load shall not induce a rate of stress increase that will exceed 130,000 pounds per square inch per minute (14.9 MPa/sec).

11.3 DELAMINATION EQUIPMENT

11.3.1 PRESSURE VESSEL

An autoclave or similar pressure vessel designed to safely withstand a pressure of at least 100-psi (0.7 MPa) is required for impregnating the specimens with water.

The pressure vessel shall be equipped with a means of obtaining a vacuum of at least 25 inches (635 mm) of mercury (at sea level), and a means of obtaining a pressure of at least 75 psi (0.52 MPa) (gauge pressure).

The vessel shall be equipped with a gauge(s) to register vacuum and pressure.

Note: A suitable vacuum may be obtained from an aspirator attached to the water supply, and 75 psi (0.52 MPa) can usually be obtained from a municipal water supply or a compressed air supply.

11.3.1.1 DRYING OVEN

The drying oven shall be capable of maintaining the conditions necessary to dry specimens to moisture content of 19% or less.

Note: These drying conditions are those obtainable in cross-flow, laboratory type ovens of the circulating type. They can also be obtained by using a non-circulating configuration in which air heated by a space heater is passed over the specimens and vented.

Conditions that affect the drying rate include cross-flow air velocity, humidity, air temperature and the arrangement, size and number of specimens in the oven.

Circulating type ovens that provide a cross-flow air velocity of 250 ±50 fpm (75±15 m/min) in the centre of the drying chamber and maintain an air temperature of 160±5°F (71±3°C) should be capable of achieving the specified drying rate.

12.0 QUALITY CONTROL MANUAL (PLANT STANDARD)

12.1 GENERAL

The Quality Control Manual (Plant Standard) is a written description of the manufacturing operation, broken down by station.

For each station in the sequence of manufacture, a description is required of the function performed by the equipment, the skills the operator requires, the responsibility of the operator in control of that station, and what checks are instituted (if required) to ensure that the equipment and operator are performing within the desired limits.

Examples of typical stations are:

a) Grade Machine set-up and off-line quality control;

b) Input grading: a station where defects are removed from the ends of the lumber prior to machining of the fingerjoint;

c) Candidate stock lumber: a detailed description of how the candidate stock is identified and stored as noted in Section 3.2;

d) Machining of the fingerjoints: this station would be concerned primarily with set-up tolerances and criteria for changing cutter heads;
e) Glue mixing: this station would be concerned with measuring the prescribed proportions of adhesive and hardener, ensuring thorough blending at acceptable temperature levels;

f) Make-up station: this station may consist of top dead rolls mounted above the in-feed table (ahead of the crowder and retard system). It provides assistance to the operator with assembly and make-up of the joint.

The Quality Control Manual shall detail all test procedures used, the wood failure criteria used (if any) and the records to be kept of in-process checks that are made. The details of the Quality Control Manual will vary with the process used. Some aspects of it may be common to all lumber sizes, grades and species groupings, while other aspects may vary with size, grade and species.

An important part of the Quality Control Manual is the special provisions for shut-down and start-up of the gluing line, particularly during temporary stoppages. The latter is of particular significance in preheat processes, in which the glue may be spread on heated wood, and has to be put under gluing pressure within a limited time to avoid precure of the glue.

Another important section covers the provisions made for the absence of any operator with specialized skills essential to the process.

In general, the Quality Control Manual specifies, in writing, one or more sets of facility operating conditions that are known to result in a product that is in continuous conformance with the requirements of this Standard. The qualification applies only to product(s) produced within the specified limits of the Quality Control Manual.

12.2 QUALITY CONTROL PERSONNEL

The quality control personnel shall be directly responsible to the facility management, and not subordinated to production or sales.

Persons responsible for quality control shall possess and demonstrate to the satisfaction of the inspection Agency that they have adequate knowledge of the manufacturing process, which shall include:

a) Inspection and test procedures used to control the process;

b) Operation and calibration of the recording and test equipment used;

c) Maintenance and interpretation of quality control records;

Also, the quality control personnel shall be responsible for carrying out and maintaining records of various inspections, and test procedures detailed in the Quality Control Manual, and for formally advising the facility management of circumstances resulting from the inspections and test procedures that indicate corrective action may be necessary in the production process.

12.3 PREPARATION, REVISION & APPROVAL

Each facility shall:

a) Prepare a Quality Control Manual in compliance with this Standard and shall submit the manual to the Agency for approval;

b) Regularly review and update its Quality Control Manual to reflect current production practices and procedures, quality control policies and quality control program procedures and resubmit to the Agency; and

c) Upon approval, implement the updated program in accordance with the Manual.

The contents of the Quality Control Manual must be approved by the Agency at the time of qualification. Qualification shall apply only to the manufacturing, quality control procedures and limits set forth in the Quality Control Manual.

The Agency shall be notified in advance of any changes in the Quality Control Manual that may affect product quality. Failure to have such changes approved prior to implementation, or failure to maintain the process in compliance to the requirements of the Quality Control Manual, shall be grounds for disciplinary action.

12.3.1 QUALITY CONTROL PROCEDURES

The Quality Control Manual shall include detailed procedures specifying how each of the following is to be performed and controlled:

a) Grading machine, FJ equipment, test equipment operation and all calibration;

b) Quality control sampling, testing and analysis;

c) Documentation and record keeping;

d) Identification and trace-ability;

e) Non-conformance; and

f) Corrective action.

12.3.2 AGENCY

The Quality Control Manual shall identify the Agency.

ALSC accredited Agencies shall include in their certification and quality control procedures, an explanation of the following:

a) That their glued lumber certification and quality control procedures comply with the ALSC Glued Lumber Policy;

b) That the responsibility for the certification and quality control procedures is that of the Agency; and

c) That the ALSC Board of Review shall monitor whether the certification and quality control procedures are being carried out by the Agency.
13.0 QUALIFICATION & SAMPLING REQUIREMENTS

13.1 GENERAL

A facility requesting initial qualification shall provide the Agency with evidence that all the requirements of Part A of this standard have been met. Upon receipt of the request, the Agency supervisor will visit the facility to determine that:

a) The facility is capable of operating within the requirements of its Quality Control Manual;

b) The facility personnel possess ability to undertake the requirements described in Section 12.0; and

c) The calibration of the grading machine (if applicable) and the test equipment conforms to the requirements of the Quality Control Manual.

Each item shall be qualified before issuing grade stamps.

Note: Delamination tests can be made on rough lumber provided delamination tests are performed on the finished product as well, and that the finished product results must be used for product quality control. This is meant to address the effect that planing may have on the fingerjoint.

13.2 QUALIFICATION REQUIREMENTS FOR ALTERNATE VQL

a) To qualify an alternate VQL that is larger than those listed in Section 6.1.2, a maximum VQL shall be specified which has the potential of being qualified. Prior to selecting the qualification samples, six (6) specimens, containing the maximum VQL to be qualified, shall be randomly selected. The specimens shall be tested with the maximum VQL positioned in the test span. Each of the six (6) specimens shall satisfy the required tension test load for the grade under consideration.

b) When an alternate VQL is qualified, the qualification sample shall include the maximum characteristic as it randomly occurs.

c) The alternate VQL shall be re-qualified whenever qualification testing is required for the grade.

13.3 NEW PRODUCTION LINE START-UP OR MAJOR CHANGE REQUIREMENTS (TO BE PERFORMED BY THE FACILITY)

During start-up of a new production line or when a major change to the fingerjoint process occurs, the facility shall immediately notify the Agency.

Prior to grade stamps being issued for lumber from the new production line or to continue gradestamping privileges in the case of a major change(s), the facility shall provide the Agency with test results of 53 test specimens performed in tension using samples generated from two consecutive shifts of operation. The specimens shall be tested in accordance with Section 9.2.1 and the test results shall satisfy the requirements set forth in Section 13.6.1.3.

The samples for these tests shall be obtained from a single size, consisting of the highest grade, a specific species or species combination and using a procedure, approved by the Agency that ensures the samples obtained are representative of the item to be qualified. The 53-specimen tension test is required in the initial start-up of a fingerjoining plant or when there is a major change to the fingerjoining process: it is intended to verify the adequacy of the joint profile chosen, and does not substitute for the Initial Qualification requirements called for in Sections 13.4 and 13.6.1.

The 53-tension test specimen can be used to determine an initial characteristic number of joint to guide the new facility in establishing this parameter. Grade stamping shall be contingent upon verification of the item in accordance with Section 13.6.

13.4 INITIAL QUALIFICATION SAMPLING (TO BE PERFORMED BY THE AGENCY)

13.4.1 FJ-MGL

The Agency supervisor shall randomly select the following for each grade to be qualified:

a) 53 specimens for the edge bending modulus of elasticity property evaluations to be tested in accordance with Section 9.1.1;

b) 53 specimens for the ultimate tensile strength evaluations (optional for Type B candidate stock with CNJ equal to 1). The samples shall be tested in accordance with Section 9.1.2.

Qualification specimens are restricted to a maximum of twenty-four feet (24') in length.

For the above two items a) & b), additional samples to increase the total of specimens to 78, 102 or 125 may be selected to qualify the minimum modulus of elasticity, and/or ultimate tensile strength.

Note: The characteristic number of joints (CNJ) in FJ-MGL manufactured from Type B candidate stock shall not exceed 1. Otherwise, the lumber shall be processed as Type A candidate stock in this Standard.

13.4.2 FINGERJOINTS

The Agency supervisor shall randomly select the following from one or more items to be qualified:

a) 20 fingerjoints for the delamination resistance tests. The sample shall be tested in accordance with Section 9.3 of this Standard.

b) Additional samples shall be selected to supplement the 53-piece tension sample in Section 13.4.1 to permit the fingerjoint tension strength assessment in accordance with Section 9.2.1.
When additional joints are required to complete the CNJ UTS - joint assessment as described in Section 9.2.1.1 for a specimen(s), the result(s) of each supplemental UTS joint assessment test shall be recorded sequentially for each of the specimens that have insufficient CNJ UTS - joint assessment tests.

The UTS joint assessment result for the specimen(s) shall be the minimum joint test result obtained from the specimen and the supplemental specimen.

c) A minimum of a 53-specimen sample shall be selected for FJ-MGL manufactured from Type B candidate stock to permit the fingerjoint tension strength assessment in accordance with Section 9.2.1 of this Standard.

For the item b) and c) above, additional samples to increase the total number of joint assessments to 78, 102 or 125 may be selected to qualify the fingerjoint tension strength.

Each qualification specimen shall meet the visual requirements in the joint area of the grade being qualified.

13.5 RE-QUALIFICATION SAMPLING

The Quality Control Supervisor shall randomly select one or more of the following samples for each item and for each property to be re-qualified:

a) 28 specimens for the edge bending modulus of elasticity property evaluations. The sample shall be tested in accordance with Section 9.1.1.

b) 28 specimens for the ultimate tensile strength evaluations (optional for Type B candidate stock with CNJ equal to 1). The sample shall be tested in accordance with Section 9.1.2.

c) 20 fingerjoints for the delamination resistance tests. The sample shall be tested in accordance with Section 9.3.

d) Sufficient samples shall be selected to permit 28 fingerjoint tension strength assessments in accordance with Section 9.2.1.

Note: Re-qualification tests are limited to those items that are deemed out of control.

For items a), b) and d), additional samples to increase the total number of specimens or joint assessments to 53 or 78 may be selected to re-qualify the minimum modulus of elasticity, ultimate tensile strength of the lumber, and/or ultimate tensile strength of the fingerjoints.

13.6 DECISION RULES

13.6.1 INITIAL QUALIFICATION RULES

Results of edge bending modulus of elasticity, tensile strength tests, fingerjoint tensile strength, and the delamination tests shall determine whether or not grade stamps may be issued for the item being qualified.

Note: If the test results meet the delamination requirement above but do not meet all the other requirements, the manufacturer may elect to qualify at a lower grade. Alternatively, adjustments to the manufacturing process may be made; new samples selected and tested until the above requirements are satisfied.

An item shall be considered qualified when all of the following requirements are met.

13.6.1.1 CHARACTERISTIC NUMBER OF JOINTS

The characteristic number of joints (See definition) shall be set at the time of qualification. It shall be not less than the maximum number found in any of the 52 of 53 specimens taken in the initial qualification sample.

Note: The characteristic number of joints as determined at the time of qualification shall be set the basis for on-going quality control. A facility may choose to qualify the process for a higher characteristic number of joints if the facility anticipates that the number of joints may increase.

13.6.1.2 FJ-MGL

a) The mean edge bending modulus of elasticity of the 53 specimen sample equals or exceeds 0.97 times $E_p$.

b) Not more than 1 of the 53 specimens has a modulus of elasticity value less than 0.82 of $E_p$ and

c) Not more than 1 of the 53 specimens has a tensile strength less than the tensile strength value listed in Table 1 for the grade. For each specimen, the tension test result shall be the result from the lumber strength assessment (Section 9.1.2).

When the additional specimen sampling procedure referred to in Section 13.4.1 is used to qualify for minimum modulus of elasticity, and tensile strength, the number of specimens below the requirements shall not exceed 2 in a 78-specimen sample; 3 in a 102-specimen sample; or 4 in a 125-specimen sample.

13.6.1.3 FINGERJOINT ULTIMATE TENSILE STRENGTH

Not more than 1 of the 53 joint assessment test results shall be less than the tensile strength value listed in Table 1 for the grade.

When the additional joint assessments referred to in Section 13.4.2 is used to qualify for the fingerjoint tensile strength, the number of joint assessment results below the requirements shall not exceed 2 in a 78-specimen sample; 3 in a 102-specimen sample; or 4 in a 125-specimen sample.

13.6.1.4 FINGERJOINT DELAMINATION

13.6.1.4.1 Specimen Delamination Conditioning & Classification

A 20 test-piece delamination sample prepared in accordance with Section 9.3.1 shall be subjected to one (1) or if required, three (3) delamination cycles following procedures outlined in Section 9.3.2 and their delamination results processed as follows:

a) After One (1) Cycle:

Test specimens with delamination of less than or equal to 5% shall be deemed as meeting the delamination resistance requirements of this Standard and do not require any further exposure to delamination cycles.
i) For Long-fingered (LF) Joints:
A long-fingered (LF) joint does not meet the delamination resistance requirements of this Standard if the delamination exceeds 15% on either test specimen. Additional exposure to delamination cycles is not required.

Note 1: For LF delamination testing, a LF joint is prepared in accordance with Clause 9.3.1.1. The LF delamination is determined by the average of the delamination results found on each half of the test specimen taken from the same joint (the sum of the delamination found on each side of the joint divided by 2).

ii) For Short-fingered (SF) Joints:
A short-fingered (SF) joint does not meet the delamination resistance requirements of this Standard if the delamination is greater than 10%. Additional exposure to delamination cycles is not required.

Note 2: For SF delamination testing, a SF joint is prepared in accordance with Section 9.3.1.2. The SF delamination is that obtained from the single test specimen.

Otherwise, the specimen(s) shall be subjected to two additional cycles for a total of three cycles.

b) After Three (3) Cycles:

i) For Long-fingered (LF) Joints:
A LF specimen does not meet the delamination resistance requirements of this Standard if the LF delamination (see Note 1) is greater than 10%, or if the delamination is greater than 15% on either half of the test specimen.

ii) For Short-fingered (SF) Joints
A SF specimen does not meet the delamination resistance requirements of this Standard if the delamination is greater than 10%.

Otherwise, the sample shall be deemed as meeting the delamination resistance requirements.

13.6.1.4.2 Evaluation of Delamination Results
The delamination resistance requirements are deemed to have been met if at least 19 of the 20 specimens for delamination meet or exceed the delamination resistance requirements assessed in accordance with Section 13.6.1.4.1 of this Standard.

13.6.2 RE-QUALIFICATION RULES

13.6.2.1 CHARACTERISTIC NUMBER OF JOINTS (CNJ)
Provided all other properties remain in-control, re-qualification for a higher characteristic number of joints shall be performed in accordance with Sections 13.5 and 13.6.2.3.

Otherwise, for FJ-MGL produced from Type A candidate stock, re-qualification for a higher characteristic number of joints shall be performed in accordance with Sections 13.4 and 13.6.2.3.

13.6.2.2 FJ-MGL
The FJ-MGL shall be considered re-qualified for Table 1 characteristic properties when the following requirements are met:

a) The mean edge bending modulus of elasticity of the 28 specimen sample equals or exceeds 0.96 times $E_g$;

b) None of the 28 specimens has a modulus of elasticity value less than 0.82 of $E_g$;

c) None of the 28 specimens have an ultimate tensile strength less than the characteristic UTS listed for the grade in Table 1.

13.6.3.3 FINGERJOINT ULTIMATE TENSILE STRENGTH
The fingerjoint shall be considered re-qualified for ultimate tensile strength when all of the joint assessment results equal or exceed the tensile strength value listed in Table 1 for the grade.

When the additional joint assessments referred to in Section 13.5 is used to qualify for the fingerjoint tensile strength, the number of joint assessment results below the requirements shall not exceed 1 in a 53-specimen sample; 2 in a 78-specimen sample; or 3 in a 102-specimen sample.

13.6.4 FINGERJOINT DELAMINATION
The fingerjoints shall be considered re-qualified for delamination resistance when the requirements of Section 13.6.1.4 are met.

13.7 INCREASED SAMPLING FOLLOWING QUALIFICATION
Immediately following qualification or re-qualification, increased sampling shall be performed for all Table 1 properties on the grades qualified.

Test results must satisfy the quality control requirements of this standard.

13.8 SUBSEQUENT QUALIFICATION

13.8.1 NEW GRADES
Separate qualification tests are required for each new item for which a grade stamp is desired.

If, however, a facility is qualified to produce a given grade, to which it desires to add a new grade, then the following shall be performed:

a) Initial qualification tests on the new grade;

b) Increased sampling, following qualification of the new grade, on both the new grade and the adjacent lower grade of the existing combination.

In clause b) above, test results shall satisfy the quality control requirements of this standard.

13.8.2 INCREASING THE CHARACTERISTIC NUMBER OF JOINTS
Subsequent qualification to increase the characteristic number of joints is only permitted for Type A candidate stock:
a) Qualification to increase the characteristic number of joints by one shall be performed in accordance with Sections 13.5d) and 13.6.2.3.

b) Otherwise, qualification for a higher characteristic number of joints shall be performed in accordance with Sections 13.4 and 13.6.2.3.

Note: FJ-MGL processed with Type B candidate stock that results in a CNJ greater than 1 shall be processed as Type A candidate stock in this Standard.

13.8.3 MAJOR CHANGES

The qualification procedures outlined in Section 13.3 shall be required for any major changes and/or process conditions, which in the opinion of the Agency may affect the quality of the product.

Note 1: Major changes may include but are not necessarily limited to: any new adhesive, a change to the joint profile, fingerjointing of green or green-frozen lumber and/or producing a grade(s) that has higher design values than those initially qualified.

Note 2: Changes in size and/or species or species combinations is not considered a major change. Requirements set forth in Section 13.4.2 are intended to deal with size and/or species changes.

13.9 NON-PRODUCTION OF QUALIFIED GRADES

When a facility does not produce a particular FJ-MGL grade for a period exceeding one year, subsequent production of that grade shall only be permitted after re-qualification is performed on the grade in accordance with Sections 13.5 and 13.6.2.

The test results shall satisfy the quality control requirements of this standard.

When a qualified facility does not produce FJ-MGL for a period exceeding one year, all grade qualifications for that facility shall become void.

The requirements for initial qualification shall be satisfied prior to further production of FJ-MGL.

13.10 NOTIFICATION REQUIREMENTS FOR DISCONTINUANCE OF QUALITY CONTROL PROCEDURES

When a grade has been qualified under the procedures for quality control of alternate VQL’s, discontinuance of the procedure requires written notification from the facility to the Agency at least one week prior to the action being implemented.

14.0 EQUIPMENT CALIBRATION

Records of all calibration checks shall be maintained for at least six (6) years.

14.1 GRADING MACHINE

A grading machine, if applicable, shall be calibrated in accordance with the procedures set forth in the Quality Control Manual.

Calibration checks shall be performed as follows:

a) At the start-up of each production shift;

b) Approximately every four (4) hours of grading machine operation thereafter or as prescribed by the grading machine manufacturer;

c) After any adjustment to the grading machine; and

d) After any maintenance to the grading machine.

</tr>
</tbody>
</table>

14.2 TEST EQUIPMENT

The test equipment shall be certified by an independent certification organisation acceptable to CLSAB prior to initial qualification and once a year thereafter.

It is the responsibility of the facility to maintain the operating condition of its test equipment in accordance with requirements set forth in their Quality Control Manual.

The test equipment shall be calibrated in accordance with procedures set forth in the Quality Control Manual and with the applicable sections in ASTM E4 and ASTM E83.

Spot-checks shall be performed at a frequency level listed in Table 6 and whenever there is reason to suspect the equipment may be out of calibration or damaged.

The Agency shall be notified immediately if damage to the test equipment or a calibration device has occurred. Re-certification of the test equipment or calibration devices by an independent certification organisation may be required by the Agency.

14.3 CALIBRATION DEVICES

An independent certification organisation acceptable to CLSAB shall certify and calibrate devices necessary to conduct the required spot-checks on the test equipment.

This is performed prior to initial qualification and once a year thereafter.

Procedures for the certification of calibration devices shall be consistent with ASTM E74 for load devices and the applicable sections in ASTM E83 for displacement devices.

A copy of all certification documents shall be made available to the Agency.
15.0 QUALITY CONTROL REQUIREMENTS

15.1 QUALITY CONTROL PROCEDURES

The quality control procedures described herein are intended to detect non-conformance in the FJ-MGL and the fingerjoints.

The properties of the FJ-MGL to be considered are mean modulus of elasticity, minimum modulus of elasticity, and tensile strength (if applicable). The properties of the fingerjoints to be considered are tension strength, and delamination. In addition, all fingerjoints are required to be proof-loaded to a tension stress level as listed in Table 1.

This Standard utilizes the Cumulative Sum (CUSUM) control chart method as one method of maintaining statistical control of the FJ-MGL ultimate tensile strength and modulus of elasticity. The criterion is based on using all of the data and not just the last few samples.

The choice of a given quality control method implies a commitment not only to the data analysis procedures but also to the sampling procedures (sample size as well as sampling frequency). The quality control procedures described in this standard are based on the CUSUM method. CUSUM parameters are included in Appendix II.

Quality control procedures other than those described (CUSUM) may be used in conjunction with this standard, provided they assure that the requirements described in Part A of this standard have been met.

The quality control procedures used by a facility shall be fully documented in their Quality Control Manual.

Note: Delamination tests can be made on rough lumber provided delamination tests are performed on the finished product as well, and that the finished product results must be used for product quality control. This is meant to address the effect that planing may have on the fingerjoint.

15.2 QUALITY CONTROL SAMPLING

15.2.1 SAMPLING METHOD

The sampling method shall be approved by the Agency and documented in the Quality Control Manual.

Specimens shall be sampled from grade stamped production. The sampling method shall include procedures for selecting the FJ-MGL specimen and which portion of the FJ-MGL will be tested for MOE and UTS.

15.2.2 SAMPLING FREQUENCY

15.2.2.1 FJ-MGL

A minimum of one five (5) specimen sample for each period of four (4) hours or less of production shall be randomly selected and tested for modulus of elasticity (MOE) and tensile strength evaluation (UTS)

Note: The UTS evaluation is optional for Type B candidate stock with CNJ equal to 1.

15.2.2.2 FINGERJOINTS

a) CHARACTERISTIC NUMBER OF JOINTS

The CNJ for each specimen and the average characteristic number of joints for each four hours of production from the 5 specimen sample selected shall be determined during this period as specified in Section 15.2.2.1.

b) TENSION TESTING

UTS joint assessment shall be performed for each of the 5 specimens identified in Section 15.2.2.1 during each four hours or part thereof of operation in accordance with Section 9.2.1.2.

c) DELAMINATION SAMPLING

There are four stages of delamination sampling:

i) Delamination Sampling Following Qualification;

ii) Level I Delamination Sampling;

iii) Level II Delamination Sampling; and

iv) Delamination Verification Sampling

i) Delamination Sampling Following Qualification

Immediately following initial qualification of a product, four joints shall be obtained from each half-shift, or part thereof, of operation for at least 500 shifts. These joints may be taken from specimens sampled for bending tests (refer to Section 9.2).

The delamination results shall be assessed in accordance with Table 7 to determine if verification sampling under Section 15.2.2.2c iv) is required.

If after 500 shifts of performing delamination sampling and testing the data shows that the facility remained “IN-CONTROL” for the last 40 shifts of production, then the facility may go on to “Level II Delamination Sampling” and testing.

ii) Level I Delamination Sampling

For Level I delamination sampling, four joints shall be obtained from each half-shift, or part thereof. These joints may be taken from pieces sampled for bending tests (See Section 9.2).

The delamination results shall be assessed in accordance with Table 7 to determine if verification sampling in accordance with Section 15.2.2.2c iv) is required.

If after performing delamination sampling and testing the data shows that the facility remained “IN-CONTROL” for the last 40 shifts of production, then the facility may go on to “Level II Delamination Sampling” and testing.

iii) Level II Delamination Sampling

For Level II Delamination Sampling and testing, one joint shall be obtained for each half-shift, or part thereof of operation.
The delamination results shall be assessed in accordance with Table 7 to determine if verification sampling in accordance with Section 15.2.2.2c) iv) is required.

iv) Verification Delamination Sampling
When verification sampling is required (See Table 7), an additional sample of 5 joints shall be randomly selected from the half-shift of production.

[1] Verification sampling pending and required only if sample joint from 2nd half-shift shows delamination greater than 5%.

[2] Verification sampling required only if sample joint from 1st half-shift shows delamination greater than 5%, or if 1st half-shift is deemed to be “OUT-OF-CONTROL”.

15.3 QUALITY CONTROL TESTING
Testing for modulus of elasticity, delamination and tensile strength (if applicable) shall be performed in accordance with the procedures described in Part A, Section 9.0 of this Standard.

15.4 ANALYSIS OF QUALITY CONTROL TESTS

Test results shall be entered on Agency approved control forms. The control forms shall be designed so that the process properties qualified under Sections 13.4 and 13.6.1 are recorded and “IN-CONTROL” and “OUT-OF-CONTROL” situations shall be readily detectable.

15.4.1 IN-CONTROL
When all of the process properties referred to in Section 15.4 remain “IN-CONTROL”, the item from which the quality control sample was drawn shall be deemed to be in compliance with the mechanical property requirements of this Standard.

15.4.2 OUT-OF-CONTROL
The requirements of this section relate to the conditions described in Appendices III and VIII to XI.
When any of the process properties described in Section 15.4 go “OUT-OF-CONTROL”, the item from which the quality control sample was drawn shall be held pending results of the following tests (if applicable):

a) FJ-MGL Verification (Visual grade, moisture content, calibration of the grading machine, grade boundary settings and calibration of the test equipment);

b) Fingerjoint Verification (delamination, UTS, characteristic number of joints).

15.4.2.1 FJ-MGL VERIFICATION
The results of the tests shall determine the course of action that shall be taken in the following manner:

RESULT A (See Appendix III (a))
When the accuracy of the visual grade, moisture content and all equipment calibrations is confirmed, requalification sampling shall be taken from continued production.
When test results indicate that the process is back “IN-CONTROL”, the held item shall be deemed to comply with the mechanical property requirements of this standard, and the production of FJ-MGL may resume. When the test results continue to show that the process is still “OUT-OF-CONTROL”, the facility shall proceed to either ACTION 1 or ACTION 2, as appropriate.
If the grading machine settings are not readily accessible to the mill, the facility shall proceed to ACTION 4.

RESULT B (See Appendix III (b))
When the accuracy of the visual grade or the moisture content is found in error and all equipment calibrations have been confirmed, the facility has the option of either immediately re-grading the held item for visual grade and/or moisture content or performing requalification sampling on the held item.
When the re-qualification sampling option is selected, the item shall be deemed to comply with the mechanical property requirements of this standard when the “IN-CONTROL” requirements have been regained. When the test results continue to show that the process is still “OUT-OF-CONTROL”, the item shall be re-graded for visual grade and/or moisture content.

Re-qualification sampling shall be performed on the residual of the re-graded FJ-MGL item. When the test results confirm that the “IN-CONTROL” requirements have been regained, the re-graded item shall be deemed to comply with the mechanical property requirements of this standard. When the test results continue to show that the process is still “OUT-OF-CONTROL”, the facility shall go to either ACTION 1 or ACTION 2, as appropriate.

RESULT C [See Appendix III (c)]

When the grading machine, if applicable, or test equipment calibration is found in error, corrective action shall be taken to correct the condition prior to further machine grading or testing being performed.

When only the test equipment calibration is found in error, an additional 5-specimen sample shall be selected and tested from the held item.

When the grading machine calibration is found in error, re-qualification sampling shall be performed from the continued production.

When the test results confirm that the “IN-CONTROL” requirements have been regained, the production of FJ-MGL may resume and the held production shall be evaluated in accordance with ACTION 3.

When the test results continue to show that the process is still “OUT-OF-CONTROL”, the facility shall go to either ACTION 1 or ACTION 2, as appropriate.

ACTION 1 [See Appendix III (d)]

When grade boundary settings are changed by 3% or less, re-qualification sampling shall be performed from continued production.

When the test results confirm that the “IN-CONTROL” requirements have been regained, FJ-MGL production may resume and the held item shall be evaluated in accordance with ACTION 3 if the equipment calibration needed adjustment.

When the test results continue to show that the process is still “OUT-OF-CONTROL”, the facility shall go to ACTION 2.

ACTION 2 [See Appendix III (e)]

When grade boundary settings are changed by more than 3% the held item shall be deemed to be in non-compliance with the requirements of this standard and all grade stamps shall be obliterated from the FJ-MGL and the candidate stock shall be re-evaluated or used to produce a lower FJ-MGL grade.

Only after appropriate action has been taken to correct the process and re-qualification sampling test results confirm that the “IN-CONTROL” requirements have been regained may the process be deemed to be back “IN-CONTROL”. Increased (double) sampling shall then be performed on the item.

ACTION 3 [See Appendix III (f)]

The quality of the held item shall be evaluated as follows:

a) When the grading machine calibration is adjusted by 2% or less or the test equipment calibration required adjustment, the held item shall be considered to comply with mechanical property requirements of this Standard.

b) When the grading machine calibration is adjusted by more than 2%, re-qualification sampling shall be performed on the held item.

When the test results confirm that the “IN-CONTROL” requirements have been regained, the held item shall be deemed to be in non-compliance with the requirements of this standard and all grade stamps shall be obliterated from the FJ-MGL.

ACTION 4 [See Appendix III (g)]

When grade boundaries are not readily accessible to the mill, obliterate grade stamps. This stock may be re-graded to a lower FJ-MGL grade for which the test results confirm that “IN-CONTROL” requirements have been met.

Only after appropriate action has been taken to correct the process and re-qualification sampling test results confirm that the “IN-CONTROL” requirements have been regained may the process be deemed to be back “IN-CONTROL”. Increased (double) sampling shall then be performed on the item.

15.4.2.2 FINGERJOINT VERIFICATION (See Appendix VIII to XI)

When the process fails to meet the requirements specified in this Standard, the facility shall be deemed to be in “OUT-OF-CONTROL” and the production as defined in Sections 15.4.2.2.1 and/or 15.4.2.2.2 and/or 15.4.2.2.3 shall be held pending the results of the following analysis and testing:

a) An examination of the test procedures, calibration and/or calculations shall be made to determine whether there were errors;

b) If no such errors are identified, proceed to Sections 15.4.2.2.1 and/or 15.4.2.2.2 and/or 15.4.2.2.3;

c) Held production deemed to be “OUT-OF-CONTROL” after evaluations in accordance with Sections 15.4.2.2.1 and/or 15.4.2.2.2 and/or 15.4.2.2.3 shall be rejected. The grade stamps from rejected production shall be obliterated or removed.
15.4.2.2.1 DELAMINATION (See Appendix VIII to IX)

a) If the average delamination of the 5-piece verification sample [Section 15.2.2.2(c) iv)] exceeds 10%, the half-shift of held production from which the samples were drawn shall be deemed to be “OUT-OF-CONTROL” for delamination.

b) When operating under Level II sampling, the first half-shift of production is permitted to be evaluated using verification sampling (Section 15.2.2.2(iv)). Otherwise, the first half-shift of production shall also be deemed to be “OUT-OF-CONTROL” for delamination.

c) If the average delamination of the 5-piece verification sample [Section 15.2.2.2(c) iv)] is less than or equal to 10%, the half-shift of held production from which the samples were drawn, and the first half-shift of production if operating under Level II sampling, shall be deemed to be “IN-CONTROL” for delamination.

d) If four or more consecutive half-shifts of production are deemed to be “OUT-OF-CONTROL” for delamination, the process shall be deemed “OUT-OF-CONTROL” for delamination and shall be re-qualified for delamination as specified with Section 13.5(c).

15.4.2.2.2 FINGERJOINT ULTIMATE TENSILE STRENGTH (UTS) (See Appendix X)

When the production represented by a specific time frame from which the quality control sample was drawn fails to meet or exceed the required characteristic minimum UTS value for the grade as listed in Table 1, production from this time frame shall be held pending the results of one – twenty-eight (28) specimen sample for fingerjoint ultimate tensile strength verification.

These confirmation samples shall be randomly selected and tested in accordance with Section 9.2.1.

If the twenty-eight (28)-specimen UTS test fails to meet the requirements of Section 13.6.2.3, the held production is “OUT-OF-CONTROL” for joint minimum tensile strength.

15.4.2.2.3 CHARACTERISTIC NUMBER OF JOINTS (CNJ) (See Appendix XI)

During production, the average characteristic number of joints for the 5-specimen quality control sample shall not exceed the characteristic number of joints at qualification and /or the CNJ for a given specimen shall not exceed by more than 1 joint than the characteristic number of joints for the qualified grade.

When the production represented by a specific time frame from which the quality control sample was drawn fails to meet the CNJ requirements, production from this time frame shall be held pending the results of one – twenty-eight (28) specimen sample for characteristic number of joints verification.

If the twenty (28) specimen characteristic number of joints test fail to meet the CNJ established in Section 13.6.1.1, the held production is deemed to be “OUT-OF-CONTROL” for characteristic number of joints.

a) Production Deemed to be “OUT-OF-CONTROL”

When the held production is deemed to be in “OUT-OF-CONTROL” after evaluation of the twenty-eight (28) specimen sample, the grade stamps from rejected production shall be obliterated or removed unless further sampling and testing is conducted in accordance with Section 15.4.2.2.3(b) below.

b) Further Assessment of Production Deemed to be “OUT-OF-CONTROL”

The facility may, at its discretion, further sample and test a twenty-eight (28)-specimen sample in accordance with Section 13.5d.

The twenty-eight (28)-specimen sample may be taken from either continued production or held production.

i) If the test results meet the requirements of Section 13.6.2.3, the held production shall be deemed “IN-CONTROL” for CNJ.

ii) If the test results fail to meet the requirements of Section 13.6.2.3, the held production shall be deemed “OUT-OF-CONTROL” for CNJ and the grade stamps from held production shall be obliterated or removed.

15.5 ALTERNATE GRADES

As a result of the number of samples obtained for qualification, it is statistically possible to qualify a grade and subsequently find that it is not possible to maintain the fingerjoint requirements of the grade.

In such a case, the facility, upon approval by the Agency, may wish to grade stamp to a lower grade for which the quality control test requirements can be satisfied.

15.6 IDENTIFICATION AND TRACEABILITY

Each package of FJ-MGL leaving the facility production line shall be identified with the time and date it left the production line. The reason for this is traceability of an item in the event that further testing is required or in the event of a non-conformance condition.

15.7 QUALITY CONTROL RECORDS

Facility control records shall include:

a) Grading machine grade boundary settings and subsequent changes to the grade level boundary settings, calibration and maintenance data (if applicable);

b) Test equipment calibration and maintenance data;

c) Quality control tests; and
16.0 REINSPECTION PROVISIONS

16.1 GENERAL

Response to complaints on FJ-MGL involving visual grade, size, moisture content, tally, fingerjoints or assigned design values, shall be based on the applicable requirements within this section of the standard, and by the requirements set forth in the NLGA Standard Grading Rules for Canadian Lumber (See Section 1.4 of this Standard).

Sample selection and testing shall be performed by the Agency whose logo appears on the lumber (or by an independent accredited testing organisation approved by the original grading Agency). Only certified test equipment calibrated to a national standard and using a process mutually agreed upon by the Agency, the seller, and the buyer shall be used.

The properties, for which conformance is required shall include the mean flexural stiffness and the minimum flexural stiffness of the FJ-MGL; the delamination resistance; and the tension strength of the fingerjoints. The property or properties under dispute shall determine the sampling and subsequent evaluation.

16.2 FJ-MGL SAMPLING AND EVALUATION

In cases of complaints pertaining to the conformance of the FJ-MGL to the assigned design values, an 80‐specimen sample shall be randomly selected. Each 80‐specimen sample shall be tested as specified in Section 9.1.1 and the results evaluated as follows:

a) The mean E of the sample shall equal or exceed 0.97 times the assigned Eₖ value;
b) In the case of FJ-MGL, not more than 6 specimens from each sample shall have an E value less than 0.82 times the Eₖ value.

16.3 FJ-MGL UTS-JOINT ASSESSMENT SAMPLING AND EVALUATION

In the cases of complaints pertaining to the FJ-MGL joint tensile strength, an 80‐specimen sample representing the item shall be randomly selected.

a) An 8‐foot section, whenever possible, shall be randomly selected from each specimen.

Note: Allowance should be made for the specimen to be gripped.

b) The number of fingerjoints tested in the UTS joint assessment (Section 9.2.1.2) for each specimen shall not be less than the number of complete fingerjoints in the 8‐foot section for the specimen. If no fingerjoints are present in the 8‐foot section, a single joint closest to the 8‐foot section shall be tested.

c) Not more than 6 specimens out of 80 shall have a UTS joint assessment result value that is less than the value listed in Table 1 for the grade.

d) For specimens that fail away from the joint (See Appendix IV - Mode 6) less than the required UTS proof stress listed in Table 1, additional joints shall be selected and tested.

16.4 FJ-MGL DELAMINATION SAMPLING AND EVALUATION

In cases of complaints pertaining to the fingerjoint delamination, a 20‐specimen sample representing the item shall be randomly selected. Specimen preparation and testing shall be in accordance with Section 9.3.

If the delamination of any specimen or, if applicable, the average delamination of a specimen and its matching specimen (Section 9.3.1.1) after one vacuum, pressure and drying cycle exceeds 5% but is less than 10%, repeat the above vacuum, pressure, drying cycle twice on that specimen and its matching specimen (if any), and record the delamination at the end of the third cycle.

Not more than 2 joints shall show greater than 15% delamination.
APPENDICES

APPENDIX I - REFERENCE MODULUS OF ELASTICITY

Since modulus of elasticity, determined in a bending test, is affected by machine deflection measuring techniques and loading application procedure, it is necessary to define a single reference procedure for calibration of quality control equipment.

The reference modulus of elasticity (E) shall be determined in accordance with ASTM D198 Standard Methods of Static Tests of Timbers in Structural Sizes. The modulus of elasticity data shall be adjusted to 15% moisture content, and to a 21 to 1 span-to-depth ratio, which is in accordance with the Standard ASTM D2915 Standard Practice for Evaluating Allowable Properties for Grades of Structural Lumber.

**Figure 8 - Failure Modes Based on ASTM D4688**
APPENDIX V - THE USE OF WOOD FAILURE ASSESSMENT IN PROCESS CONTROL

In this Standard, control of the quality of the gluing is resistance to delamination. However, the results from a delamination test take time. During the start-up, and during periods in which the manufacturing facility goes “Out-of-Control” for no obvious reason, the quality of the glueline may be assessed more rapidly by assessing the wood failure developed in the fingerjoint. In processes using heat to accelerate the cure of the glueline, wood failure may be assessed within a short period of time after assembly of the glued joint, usually within 5 to 15 minutes. This wood failure assessment may be used as a diagnostic tool to identify malfunctions in the manufacturing process.

The significance of wood failure is that it correlates inversely with delamination resistance. If a high degree of wood failure develops, the joint should be resistant to delamination. Conversely, any area in the joint that shows no wood failure may be prone to delaminating in the delamination test.

In this Standard, wood failure shall mean that the joint fails in a shallow layer of the wood next to the glueline. In testing fingerjoints, the difficulty with a wood failure test procedure is a tendency for some of the fingers to break off at the base rather than pull out of the joint. Such broken fingers are not classed as wood failure, but are indeterminate, since the glueline under the finger was not stressed in shear parallel to the glueline.

Another observation of interest is not wood failure, but glue failure. Ordinary glue failure is a failure in the glueline itself, so that glue is visible on both matching surfaces of the joint. In hot set joints made with phenol-resorcinol glue, a common cause is thick gluelines in which the glue boils out. This may result from inadequate pressure, which in turn may result from a slip in the roller press, improper machining of the joint, or from dirt in the joint, which prevents the joint from squeezing together properly. Another cause for glue failure is pre-cure of the glue in circumstances in which the glue is spread on both end of a heated fingerjointed piece. This pre-cure may affect the whole joint or may be restricted to areas in the joint that received an inadequate spread of the glue as a result of glue wipe in the glue spreader.

Another type of failure is adhesion failure, in which the glueline fails not in the glueline, but at the surface of the wood. In such a failure, the glue is visible on one side of the glueline but the matching area on the other side of the glueline is bare wood or wood lightly stained by the glue. Common causes of this is pre-cure of the glue spread on one end of the piece of heated wood, due either to inadequate glue spread in all or part of the joint, or in holding the glue spread pieces too long before assembly.

Both types of failure (cohesion failure and adhesion failure) must be distinguished from glue skip, in which a portion of the joint gluing surfaces receives no glue at all. This is not a glue failure, however any such area may be vulnerable to delamination.

The technique used to open the joint with minimum breakage of the fingers is to fail the joint in bending at right angles to the line of the fingers: e.g. flat bending of a horizontal fingerjoint. The piece is subjected to a bending load until approximately half of the fingers on the tension face are pulled open. The piece is then turned over and a bending load again applied to pull open the remaining fingers. In hot set joints, less finger breakage is obtained if the joint is broken open as soon as the glue has hardened. It is particularly important that the entire joint be broken open in flat bending.

If the testing machine does not have sufficient displacement capacity, the partially failed joint can be broken completely open by resting it on two supports and applying sufficient force to pull open the joint.

Wood failure is not a mandatory requirement of this Standard. However Section 7.4.1 requires that sufficient glue must be applied to the joint.

APPENDIX VI - AGENCY ADMINISTRATION

This Standard shall be administered by an accredited Agency. Agency approval of a facility to grade stamp fingerjointed lumber shall be contingent upon the facility’s compliance with the procedures and requirements of this Standard.

Inspections shall include amongst other things reporting on the following:

a) Examination of samples from the facility’s inventory, the facility’s records and procedures, to verify compliance to the requirements of Part A of this Standard and the Plant Standard.

b) Examination of the bending and tension test equipment and the proof loading equipment including observations on:
   i) wear and damage;  
   ii) lubrication and operations of moveable parts;  
   iii) record of weekly calibration

c) Examination of the delamination test equipment, including the apparatus for measuring temperature, pressure and time, and the drying chamber.

d) Inspection of the glue mixing equipment and procedures, including the accuracy of the weighing equipment, mixing proportions, and cleanliness of the facility.

e) Verification of the delamination measurement and procedures.

f) Examination of the control system used to prevent overheating of the wood in the gluing surface.

a) Evaluation of Delamination Results after Qualification
   (Row 1 - Columns 3 & 4)
If following qualification and after one vacuum-pressure-dry cycle, all four joint samples show average delamination greater than 5% but less than 10% (Column 3), OR one or more of the four joints show average delamination greater than 10% (Column 4), the half-shift production where the joints were taken will have to be re-sampled for verification testing.

b) Evaluation of Level I Delamination Results
   (Row 2 - Columns 3 & 4)
If under Level I delamination sampling and after one vacuum-pressure-dry cycle, all four joint samples show average delamination greater than 5% but less than 10% (Column 3), OR one or more of the four joints show average delamination greater than 10% (Column 4), the half-shift production where the joints were taken will have to be re-sampled for verification testing.

c) Evaluation of Level II 1st Half-Shift Delamination Results
   (Row 3 – Columns 3 & 4)
If under Level II delamination sampling and after one vacuum-pressure-dry cycle, the single joint sample taken in the first half shift shows average delamination of 5% but less than 10% (Column 3), take no action but wait for the result of the second half shift joint sample. However, if the single joint sample shows average delamination greater than 10% (Column 4), then the first half shift production where the joint was taken will have to be re-sampled for verification testing.

d) Evaluation of Level II 2nd Half-Shift Delamination Results
   (Row 4 – Columns 3 & 4)
If under Level II delamination sampling and after one vacuum-pressure-dry cycle, the single joint sample taken in the second half shift also shows average delamination of 5% but less than 10% (Column 3), OR if the single joint sample shows average delamination greater than 10% (Column 4), the second half shift production where the joint was taken will have to be re-sampled for verification testing. In addition, the first half shift production will also have to be re-sampled for verification testing if it has not already been re-sampled under Row 3 above.
General Instruction No. 1

NLGA - SPS 4

November 2014

NLGA Special Product Standard SPS 4 consists of 40 pages, each dated “November 2014”

This Standard, like all NLGA Standards, is subject to periodic review and may be amended from time to time.

Check the publication section of our website (www.nlga.org) for the date of the latest edition of NLGA SPS 4.

<td>Under-sizing</td>
<td>Q. Can 1-7/16 X 3-7/16 undersize grade stamp could be used on SPS 4 lumber if the under sized product was qualified as a stand-alone item?</td>
<td>A. If a mill wishes to undersize SPS 4 lumber to clean up glue-spread etc. then the under-sized product must be qualified as a separate item and stamped as undersized product. The test loads applied to the under-sized lumber must be increased to the full-sized (i.e. 1-1/2 x 3-1/2) test load.</td>
